I am not the biggest fan of IBCM. I thought it was really hard to use and I'm still not very sure I have it all down. I thought it would make more sense to have the memory addresses before the opcode, so it would be easier to tell what values are stored in each memory address. I really am not sure of storing subroutines, I do not think I could do that correctly on a test. I don't think making any changes to the simulator is necessary, it's very nice to be able to debug in the simulator. However, I think finding a way to run ibcm on the command line would be really cool, though I'm sure that's pretty complicated and would sacrifice the debugging of the simulator. I do not feel super confident writing in ibcm, though hopefully I am able to brush up on it before test time. I do not anticipate writing another line of machine code after taking this class.
